Abstract

We present a homogenization model for a single row of locally resonant inclusions. The resonances, of the Mie type, result from a high contrast in the shear modulus between the inclusions and the elastic matrix. The presented homogenization model is based on a matched asymptotic expansion technique; it slightly differs from the classical homogenization which applies for thick arrays with many rows of inclusions (and thick means large compared to the wavelength in the matrix). Instead of the effective bulk parameters found in the classical homogenization, we end up with interface parameters entering in jump conditions for the displacement and for the normal stress; among these parameters, one is frequency dependent and encapsulates the resonant behavior of the inclusions. Our homogenized model is validated by comparison with results of full wave calculations. It is shown to be efficient in the low frequency domain and accurately describes the effects of the losses in the soft inclusions.

Keywords:

1. Introduction

Metamaterial structures are constructed by repeating, most often periodically, a unit cell. They may have a lattice periodicity of the same order of magnitude than the working wavelength, resulting in a structure of the crystal type; such structures present resonant behaviors due to Bragg scattering mechanism. In the 2000's, resonant structures with subwavelength unit cells have been proposed in the context of elasticity (Liu et al., 2000) and in the context of electromagnetism (O'Brien and Pendry, 2002). In this case, the resonances are attributable to an inclusion placed in the unit cell and presenting a high contrast in its material properties with respect to the surrounding matrix. These resonances often referred to as Mie resonances occur at frequencies producing a wavelength in the inclusion comparable to the inclusion size (and this size is much

smaller than the wavelength in the matrix). The ability of these so-called locally resonant structures to forbid the wave propagation has been exhibited and the forbidden band gaps have been interpreted in terms of an effective negative parameter being the mass density in elasticity (Liu et al., 2000) and the permeability in electromagnetism (O'Brien and Pendry, 2002). Since then, locally resonant materials have been intensively studied for applications including the design of efficient wave shields (Goffaux et al., 2002; Ho et al., 2003), absorbers of small thicknesses (Goffaux et al., 2004; Zhao et al., 2010; Brunet et al., 2013) and subwavelength waveguides (Achaoui et al., 2011; Jin et al., 2016).

Because of their subwavelength scales, homogenization approaches are well adapted to describe the effective properties of such structures. As primarily proposed in Liu et al. (2000) and in O'Brien and Pendry (2002), the thickness of the resonant material was large compared to any wavelength outside the inclusions so that the bulk effect of this massive structure on the wave propagation was regarded. In this context, extensions of the classical homogenization to high contrast versions have been proposed in elasticity by Auriault (1994) and Auriault and Boutin (2012) and in electromagnetism by Zhikov (2000, 2005); Felbacq and Bouchitté (2005); Bouchitté et al. (2009). These high contrast homogenizations provide effective bulk parameters among which the effective mass density or permeability is frequency dependent and may change in sign as a result. It is worth noting that, in the two contexts of waves, the constitutive equations being respectively the Navier equations and the Maxwell equations differ but the conclusions are of the same nature and conform to the expectations (we refer to "expectations" the expected negative parameters previously obtained using retrieval methods). Note also alternative methods based on computational homogenization (Pham et al., 2013). *A priori*, the story should end here.

Figure 1: The array composed of a single row of locally resonant inclusions with material properties (ρ_i, G_i) embedded in an elastic matrix with (ρ_m, G_m) .

However, motivated by the design of compact metamaterial devices and following the intuitive argument that each local resonator vibrates almost like an independent unit, structures involving a single row of resonators or few rows have been thought, see *e.g.* Ho et al. (2003), Zhao et al. (2010). In this case, interrogating the bulk response of the device becomes questionable. Indeed, when the number of cells is too small, the metamaterial device is dominated by boundary layer effects and the response of its bulk is not pertinent anymore; the failure of the effective medium theories for thick structures has been illustrated recently in Lapine et al. (2016) and in Marigo and Maurel (2016a), Marigo and Maurel (2016b) (non resonant structures were considered in these references). Homogenization approaches able to handle such thin structures have been developed originally in the context of solid mechanics (Sanchez-Palencia, 1987; Bakhvalov and Panasenko, 1989; Marigo and Pideri, 2011). In the context of wave propagation, they have been adapted in geophysics (Capdeville and Marigo, 2013), in acoustics (Bonnet-Bendhia et al., 2004; Marigo and Maurel, 2016a,b) and in electromagnetism (Delourme et al., 2012; Delourme,

2015; Maurel et al., 2016; Marigo and Maurel, 2016c), see also (Felbacq, 2015). Here, we extend these works to the case of an array composed of a single row of locally resonant inclusions (Fig. 1). We restrict ourselves to the case of two dimensional shear wave propagation, which reduces our conclusions to a scalar case but make them applicable to the case of polarized electromagnetic waves as considered in Felbacq and Bouchitté (2005); note that the extension to the three dimensional case is quite easy in elasticity but more tricky in electromagnetism.

The homogenized model is presented in Section 2; it basically relies on the same ingredients than the classical homogenization, a two scale method and an asymptotic expansion of the solution. The solution is expressed in a rescaled, or renormalized, structure accounting for a small parameter

$$\eta \equiv kh \ll 1, \quad (1)$$

(k is the wavenumber in the matrix and h the spacing between the inclusions in the row) and accounting for the high contrast in the shear modulus; this latter has to scale as $1/\eta^2$ to produce wavelengths in the inclusions of the order of h . In addition, it accounts for the small thickness of the device and this is done by using two different expansions near and far from the array, which are connected using so-called matching conditions. The homogenization is conducted up to $O(\eta^2)$ and it makes effective interface parameters to appear, which enter in jump conditions on the displacement and on the normal stress across an equivalent interface whose interior region is disregarded (Fig. 2). In the present case, we obtain six interface parameters among which one is frequency dependent. The homogenized problem is validated in Section 3 by comparison with full wave calculations in two cases of interest: first we inspect the scattering by such thin metafilms for a plane wave at oblique incidence, afterwards the ability of the array to support guided waves is regarded. In both cases, the effect of losses within the inclusions is considered (the effect of the losses in the matrix is trivial and it is disregarded). The homogenized problem can be solved explicitly, yielding the scattering coefficients and of the dispersion relation of the guided waves, respectively in the two problems.

Figure 2: In the homogenized problem, the row of inclusions is replaced by an equivalent thick interface. Across the interface, jump conditions apply, Eq. (3), and the region inside the interface $|X_1| < e/2$ is disregarded.

2. The real and the homogenized problems

We consider two dimensional shear waves propagating in an elastic matrix containing a single row of periodically located elastic inclusions with spacing h and thickness $e = O(h)$ (Fig. 1). The mass density ρ and the shear modulus G are spatially varying parameters being piecewise

constants; in the matrix, $\rho(\mathbf{X}) = \rho_m$, $G(\mathbf{X}) = G_m$ and in the inclusions $\rho(\mathbf{X}) = \rho_i$, $G(\mathbf{X}) = G_i$. In the harmonic regime, the elastic displacement U has a time dependence $e^{-i\omega t}$ with ω the frequency (the time dependence will be omitted in the following), and the wave equation reads

$$\begin{cases} \operatorname{div} \Sigma + \rho \omega^2 U = 0, & \Sigma = G \nabla U, \\ \text{with } U \text{ and } \Sigma \cdot \mathbf{n} \text{ being continuous at each interface matrix/inclusion.} \end{cases} \quad (2)$$

With $k = \omega \sqrt{\rho_m/G_m}$ the wavenumber in the matrix, the low frequency regime concerns the frequency range for which $\eta \equiv kh \ll 1$. Next, we are interested in resonances in the inclusions and this is possible if $k_i h = O(1)$, with $k_i = \omega \sqrt{\rho_i/G_i}$ the wavenumber in the inclusions. We shall consider a low contrast in the mass density $\rho_i/\rho_m = O(1)$ and a high contrast in the shear modulus with $G_i = \eta^2 G_0$ and $G_0/G_m = O(1)$.

High contrasts in the shear moduli are easy to obtain; rubbers and silicon rubbers offer a variety of shear modulus values ranging from 10^4 to 10^7 Pa with roughly the same density $\rho \simeq 1300 \text{ kg.m}^{-3}$, see *e.g.* Lai et al. (2011), and obviously stiffer materials exist with a similar mass density. In electromagnetism for transverse magnetic polarization (the magnetic field plays the role of U in (2)), the situation is the same. In this case, the permeability plays the role of ρ and the permittivity plays the role of G ; therefore, non magnetic dielectric materials offer a class of materials with the same permeability (the one of the vacuum) and possibly high contrasts in the permittivity, see *e.g.* Campione et al. (2012). The story is different for acoustic waves in fluids; the propagation of these longitudinal waves is described by the linearized Euler equations, yielding $\operatorname{div} \left(\frac{\nabla P}{\rho} \right) + \frac{\omega^2}{B} P = 0$, with P the acoustic pressure, ρ the mass density and $B = \rho c^2$ the bulk modulus. However, if a high contrast in the mass density can be obtained, for instance between gases and liquids, the sound speeds are of the same order of magnitude in most fluids; it results that the wavelengths cannot be tuned differently by playing on the material properties (B and ρ scale the same). This particularity has practical consequences when comparing the acoustic metamaterials and their electromagnetic/elastic counterparts (Cordero et al., 2015; Mercier et al., 2015) and other strategies to obtain local resonances have to be found; these can consist in using elastic inclusions in liquids (Ding et al., 2007) or exploiting other type of resonances, for instance Minnaert resonances (Bretagne et al., 2011) or the resonances of the Helmholtz type (Guenneau et al., 2007; Elford et al., 2010).

We come back to our problem and its homogenized counterpart. We shall see that the row of inclusions can be described by an equivalent layer, or an enlarged interface, with the same thickness and associated to jump conditions relating the values of the homogenized field on its both sides (Fig. 2). Specifically, for inclusions with simple symmetry shape, the homogenized problem consists in solving

$$\begin{cases} \Delta U^h + k^2 U^h = 0, & |X_1| > \frac{e}{2}, \\ \text{Jump conditions} \begin{cases} \llbracket U^h \rrbracket_e = h\mathcal{B} \frac{\partial U^h}{\partial X_1}, \\ \left[\left[\frac{\partial U^h}{\partial X_1} \right] \right]_e = hS \frac{\partial^2 U^h}{\partial X_1^2} + hC \frac{\partial^2 U^h}{\partial X_2^2} - h\mathcal{D}(k) k^2 \bar{U}^h, \end{cases} \end{cases} \quad (3)$$

where we defined, for any field f , $\llbracket f \rrbracket_e \equiv f^+ - f^-$ and $\bar{f} \equiv (f^+ + f^-)/2$, with $f^\pm \equiv f(\pm e/2, X_2)$.

The effective parameters $(\mathcal{B}, \mathcal{C}, \mathcal{S})$ depend only on the geometry of the inclusions while $\mathcal{D}(k)$ has an additional dependence on the frequency and it is the parameter which encapsulates the possible resonances of the Mie type. For instance, for rectangular shape of inclusion, as we shall consider in the numerical example, we have

$$\begin{cases} \mathcal{B} = \frac{e/h}{1-\varphi} - \frac{2}{\pi} \log \left(\sin \frac{\pi(1-\varphi)}{2} \right), \\ \mathcal{C} \simeq \frac{e}{h} (1-\varphi) - \frac{\pi}{8} (1-\varphi)^2, \\ \mathcal{S} = \frac{e}{h} (1-\varphi), \end{cases} \quad (4)$$

where $h\varphi$ is the length of the rectangular inclusion along X_2 (see forthcoming Section 3), and

$$\begin{cases} \mathcal{D}(k) = \frac{\rho_i}{\rho_m} \frac{e\varphi}{h} \left[1 - \sum_n \alpha_n^2 \frac{k_i^2}{k_i^2 - k_{i,n}^2} \right], \\ \text{with } n = (n_1, n_2), \quad k_{i,n}^2 \equiv \left(\frac{n_1 \pi}{e} \right)^2 + \left(\frac{n_2 \pi}{h\varphi} \right)^2 \quad \text{and} \quad \alpha_n \equiv \frac{8}{\pi^2 n_1 n_2}. \end{cases} \quad (5)$$

In the following, a more general form of the homogenized problem is derived for non symmetric inclusions, Eqs. (44) with basically the same conclusion. Note that the above system does not interrogate the region $|X_1| < e/2$, where the solution does not need to be defined.

Finally, the problems (2) and (3) have to be associated to boundary conditions at $|\mathbf{X}| \rightarrow +\infty$. These boundary conditions are in general radiation conditions of the Sommerfeld type, which select outgoing scattered waves once the incident wave has been defined. We do not need to specify them for the time being.

2.1. The rescaled outer and inner problems

To begin with, the real problem (2) is written using the non-dimensional coordinates $\mathbf{x} \equiv k\mathbf{X}$, with k the wavenumber in the matrix ($k^2 = \rho_m \omega^2 / G_m$). We define the fields

$$u(\mathbf{x}) \equiv U(\mathbf{X}), \quad \sigma(\mathbf{x}) \equiv \frac{1}{kG_m} \Sigma(\mathbf{X}), \quad (6)$$

and the spatially dependent parameters

$$a(\mathbf{x}) \equiv \frac{\rho(\mathbf{X})}{\rho_m}, \quad b(\mathbf{x}) \equiv \frac{G(\mathbf{X})}{G_m}, \quad (7)$$

being the relative mass density and shear modulus. Thus, we have $a(\mathbf{x}) = 1 = b(\mathbf{x})$ in the matrix, and with $G_i = \eta^2 G_0$, $a(\mathbf{x}) = a_i = \rho_i / \rho_m$ and $b(\mathbf{x}) = b_i = \eta^2 b_0$ in the inclusions (with $b_0 = G_0 / G_m$). In $\mathbf{x}$ coordinate, the system (2) reads

$$\begin{cases} \operatorname{div} \sigma + au = 0, \end{cases} \quad (8a)$$

$$\begin{cases} \sigma = b \nabla u, \end{cases} \quad (8b)$$

$$\begin{cases} u \text{ and } \sigma \cdot \mathbf{n} \text{ continuous at the inclusions/matrix interface.} \end{cases} \quad (8c)$$

Next, we shall use two systems of coordinates, $\mathbf{x} = k\mathbf{X}$ and $\mathbf{y} \equiv \mathbf{X}/h$ (whence $\mathbf{y} = \mathbf{x}/\eta$); they account respectively for slow variations of the wavefield (the macro scale being the wavelength in the matrix) and for the rapid variations of the wavefield (the micro scale associated to the subwavelength structure of the row). Obviously, the dependance of the fields (u, σ) on $\mathbf{x}$ and $\mathbf{y}$ is pertinent or not, depending on how close we are to the inclusions. Sufficiently far away from the row, only the propagating field is associated to variations of u and σ on the scale of the wavelength $1/k$; thus, only $\mathbf{x}$ is needed. In the near field, the wavefield is more complex since it experiences (i) rapid variations of the evanescent field, being associated to all the scales between $1/k$ and h and (ii) slow variations in $1/k$, associated to the propagating field along x_2 (for instance through the condition of the quasi-periodicity for plane waves). Thus, the rapid variations in the near field problem are handled by the coordinates $\mathbf{y}$ and to account for the slow variations, we keep x_2 as additional coordinate.

From what has been said, the expansions of the solution are written differently in the two regions; we use in the far field, also named outer region, the following expansions

$$\begin{cases} u = u^0(\mathbf{x}) + \eta u^1(\mathbf{x}) + \dots, \\ \sigma = \sigma^0(\mathbf{x}) + \eta \sigma^1(\mathbf{x}) + \dots \end{cases} \quad (9)$$

and in the near field, or inner region,

$$\begin{aligned} \text{in } \Omega \setminus \Omega_i & \begin{cases} u = v^0(\mathbf{y}, x_2) + \eta v^1(\mathbf{y}, x_2) + \dots, \\ \sigma = \tau^0(\mathbf{y}, x_2) + \eta \tau^1(\mathbf{y}, x_2) \dots \end{cases} \\ \text{in } \Omega_i & \begin{cases} u = v_i^0(\mathbf{y}, x_2) + \eta v_i^1(\mathbf{y}, x_2) + \dots, \\ \sigma = \tau_i^0(\mathbf{y}, x_2) + \eta \tau_i^1(\mathbf{y}, x_2) \dots \end{cases} \end{aligned} \quad (10)$$

(Fig. 3 shows the rescaled inner domains Ω and Ω_i in $\mathbf{y}$ coordinates). As in the classical homogenization, the fields v^n and τ^n , $n = 0, \dots$, are assumed to be periodic with respect $y_2 \in (0, 1)$ and this is not meaningless in the present context since the condition of pseudo-periodicity is handled by the variables x_2 (thus, we recognize Floquet type solutions for (v^n, τ^n)).

Figure 3: Rescaled domains Ω_i and Ω . In Ω , $\mathbf{y} \in (-y_1^m, y_1^m) \times (0, 1)$ and in practice, the limit $y_1^m \rightarrow +\infty$ will be considered.

In the following, (8) will be written at each order using the differential operators

$$\begin{cases} \nabla \rightarrow \nabla_{\mathbf{x}}, & \text{in the outer region,} \\ \nabla \rightarrow \frac{1}{\eta} \nabla_{\mathbf{y}} + \mathbf{e}_2 \frac{\partial}{\partial x_2}, & \text{in the inner region.} \end{cases} \quad (11)$$

In the outer region, (8a)-(8b) apply at each order (with $a(\mathbf{x}) = 1 = b(\mathbf{x})$). We shall need the orders $n = 0$ and 1, for which

$$\begin{cases} \operatorname{div} \boldsymbol{\sigma}^n + u^n = 0, \\ \boldsymbol{\sigma}^n = \nabla u^n. \end{cases} \quad (12a)$$

$$(12b)$$

In the inner regions $\Omega \setminus \Omega_i$ and Ω_i , (8) takes different forms at each order using (11) with a and b given by

$$\begin{cases} a(\mathbf{y}) = 1 = b(\mathbf{y}), & \text{in } \Omega \setminus \Omega_i, \\ a(\mathbf{y}) = a_i, \quad b(\mathbf{y}) = \eta^2 b_0, & \text{in } \Omega_i. \end{cases} \quad (13)$$

2.2. Boundary conditions and matching conditions between the inner and outer solutions

By construction, the inclusions are seen by the inner solution only; the continuity of the displacement and of the normal stress at the interface $\partial\Omega_i$ apply at each order, with

$$v^n|_{\partial\Omega_i} = v_i^n|_{\partial\Omega_i}, \quad \text{and} \quad \boldsymbol{\tau}^n \cdot \mathbf{n}|_{\partial\Omega_i} = \boldsymbol{\tau}_i^n \cdot \mathbf{n}|_{\partial\Omega_i}, \quad n = 0, 1, \dots \quad (14)$$

Reversely, the boundary conditions at $|\mathbf{x}| \rightarrow +\infty$ apply to the outer solution only. It follows that boundary conditions for $|y_1| \rightarrow +\infty$ are missing in the inner problem and they are missing for $x_1 \rightarrow 0^\pm$ in the outer problem. These conditions are provided by the matching conditions; they ensure the continuity of u and $\boldsymbol{\sigma}$ in an intermediate region where the evanescent field can be considered as negligible. It is $y_1 \rightarrow \pm\infty$ for the near field solution and it is $x_1 \rightarrow 0^\pm$ for the far field solution. Owing to the Taylor expansion, $u^0(x_1, x_2) = u^0(0, x_2) + x_1 \partial_{x_1} u^0(0, x_2) + \dots = u^0(0, x_2) + \eta y_1 \partial_{x_1} u^0(0, x_2) + \dots$ (same for $\boldsymbol{\sigma}^0$), we get at order 0

$$\begin{cases} u^0(0^\pm, x_2) = v^0(\pm\infty, y_2, x_2), \\ \boldsymbol{\sigma}^0(0^\pm, x_2) = \boldsymbol{\tau}^0(\pm\infty, y_2, x_2), \end{cases} \quad (15a)$$

$$(15b)$$

and at order 1,

$$\begin{cases} u^1(0^\pm, x_2) = \lim_{y_1 \rightarrow \pm\infty} \left[v^1(\mathbf{y}, x_2) - y_1 \frac{\partial u^0}{\partial x_1}(0^\pm, x_2) \right], \\ \boldsymbol{\sigma}^1(0^\pm, x_2) = \lim_{y_1 \rightarrow \pm\infty} \left[\boldsymbol{\tau}^1(\mathbf{y}, x_2) - y_1 \frac{\partial \boldsymbol{\sigma}^0}{\partial x_1}(0^\pm, x_2) \right]. \end{cases} \quad (16a)$$

$$(16b)$$

The boundary conditions for the outer solution at $x_1 = 0^\pm$ will provide the jump conditions that we are looking for, and from (15)-(16), they require the inner solution to be known. Also, we shall see that relevant jump conditions require to go at order 1, and the orders 0 and 1 refer to the order of the outer solution.

2.3. The jump conditions at order 0

We start with the inner problem. In $\Omega \setminus \Omega_i$, Eqs. (8a)-(8b) at order η^{-1} along with (13) give

$$\nabla_{\mathbf{y}} v^0 = \mathbf{0}, \quad \operatorname{div}_{\mathbf{y}} \boldsymbol{\tau}^0 = 0, \quad \text{in } \Omega \setminus \Omega_i, \quad (17)$$

and in Ω_i , (8b) at order η^0 and (13) give

$$\boldsymbol{\tau}_i^0 = \mathbf{0}, \quad \text{in } \Omega_i. \quad (18)$$

The first equation of (17) tells us that v^0 does not depend on y , and we deduce from the matching condition (15a) that u^0 is continuous at $x_1 = 0$ with

$$v^0(x_2) = u^0(0^\pm, x_2). \quad (19)$$

Now, we integrate over $\Omega \setminus \Omega_i$ the relation $\operatorname{div}_y \tau^0 = 0$ from (17). Owing to (i) $\tau^0 \cdot \mathbf{n}|_{\partial\Omega_i} = \tau_i^0 \cdot \mathbf{n}|_{\partial\Omega_i} = 0$ from (14) and (18), and owing to (ii) the periodicity of τ^0 with respect to y_2 , we get

$$\int dy_2 \tau_1^0(y_1^m, y_2, x_2) = \int dy_2 \tau_1^0(-y_1^m, y_2, x_2),$$

(when integrating over y_2 , we consider implicitly $y_2 \in (0, 1)$). Taking the limit $y_1^m \rightarrow +\infty$, the matching conditions (15b) gives the continuity of the normal component to the interface of σ^0 , namely

$$\sigma_1^0(0^+, x_2) = \sigma_1^0(0^-, x_2), \quad (20)$$

(note that the matching conditions (15b) have been integrated with respect to $y_2 \in (0, 1)$). At this leading order, the row of inclusions is transparent for the wave and we shall consider the next order to get the effect of the array.

2.4. The jump conditions at order 1

2.4.1. The Neumann elementary problems and the jump condition on u^1

The jump condition on u^1 requires only the solution v^1 in $\Omega \setminus \Omega_i$ to be determined and we shall see that v^1 is independent of the solution in Ω_i at this order. The problem satisfied by v^1 reads

$$\text{in } \Omega \setminus \Omega_i \begin{cases} \operatorname{div}_y \tau^0 = 0, & \tau^0 = \nabla_y v^1 + \frac{\partial u^0}{\partial x_2}(0, x_2) \mathbf{e}_2, \\ \tau^0 \cdot \mathbf{n}|_{\partial\Omega_i} = 0, \\ \lim_{y_1 \rightarrow \pm\infty} \tau^0 = \frac{\partial u^0}{\partial x_1}(0, x_2) \mathbf{e}_1 + \frac{\partial u^0}{\partial x_2}(0, x_2) \mathbf{e}_2. \end{cases} \quad (21)$$

In the above system, the equilibrium and the constitutive relation followed from (17) and (8b) at order η^0 along with (13) and $v^0(x_2) = u^0(0, x_2)$, Eq. (19). The boundary condition on $\partial\Omega_i$ is deduced from (14) using (18). Finally, the limit values for $y_1 \rightarrow \pm\infty$ are given by the matching conditions (15b) and provide the last conditions needed to solve the problem on v^1 up to a term which depends only on x_2 . The problem on v^1 appears to be linear with respect to $\partial_{x_1} u^0(0, x_2)$ and $\partial_{x_2} u^0(0, x_2)$. Specifically, let us write

$$v^1(\mathbf{y}, x_2) = \frac{\partial u^0}{\partial x_1}(0, x_2) V^{(1)}(\mathbf{y}) + \frac{\partial u^0}{\partial x_2}(0, x_2) V^{(2)}(\mathbf{y}) + \tilde{v}(x_2). \quad (22)$$

It is easy to see that v^1 is solution of the problem if $V^{(i)}$, $i = 1, 2$ satisfy

$$\begin{cases} \Delta V^{(1)} = 0, \\ \nabla V^{(1)} \cdot \mathbf{n}|_{\partial\Omega_i} = 0, \\ \lim_{y_1 \rightarrow \pm\infty} \nabla V^{(1)} = \mathbf{e}_1, \end{cases} \quad \begin{cases} \Delta V^{(2)} = 0, \\ [\nabla V^{(2)} + \mathbf{e}_2] \cdot \mathbf{n}|_{\partial\Omega_i} = 0, \\ \lim_{y_1 \rightarrow \pm\infty} \nabla V^{(2)} = \mathbf{0}. \end{cases} \quad (23)$$

These two elementary Neumann problems are independent of the incident wave u^0 , contrary to v^1 in (21). Incidentally, they are the same as those encountered when considering a row of cracks or of voids (Marigo and Maurel, 2016a,c); thus, it is clear that they will not encapsulate the possible resonances of the soft inclusions.

From (23), $V^{(1)}$ and $V^{(2)}$, being defined up to a constant, can be chosen in the form

$$V^{(1)}(\mathbf{y}) = \begin{cases} y_1 + V_{\text{ev}}^{(1)}(\mathbf{y}), & y_1 < 0 \\ y_1 + \mathcal{B}_1 + V_{\text{ev}}^{(1)}(\mathbf{y}), & y_1 > 0, \end{cases} \quad V^{(2)}(\mathbf{y}) = \begin{cases} V_{\text{ev}}^{(2)}(\mathbf{y}), & y_1 < 0 \\ \mathcal{B}_2 + V_{\text{ev}}^{(2)}(\mathbf{y}), & y_1 > 0, \end{cases} \quad (24)$$

where $V_{\text{ev}}^{(i)}(\mathbf{y})$, $i = 1, 2$ are evanescent fields, vanishing at $y_1 \rightarrow \pm\infty$. Thus, $\mathcal{B}_1 = \lim_{y_1 \rightarrow +\infty} (V_{\text{ev}}^{(1)}(\mathbf{y})) - y_1$ and $\mathcal{B}_2 = \lim_{y_1 \rightarrow +\infty} V_{\text{ev}}^{(2)}(\mathbf{y})$, with $\mathcal{B}_i$ being constant values ($i = 1, 2$). Now, it is sufficient to use the matching condition (16a) to get

$$[[u^1]]_0 = \mathcal{B}_1 \frac{\partial u^0}{\partial x_1}(0, x_2) + \mathcal{B}_2 \frac{\partial u^0}{\partial x_2}(0, x_2), \quad (25)$$

which provides the first jump condition written here for u^1 across a zero thickness interface at $x_1 = 0$.

2.4.2. The resonant Dirichlet elementary problem and the jump condition on σ^1

The derivation of the jump condition on σ^1 is more demanding and requires the solution v_i^0 to be determined in Ω_i . The solution v_i^0 satisfies

$$\text{in } \Omega_i \quad \begin{cases} \text{div}_y \tau_i^1 + a_i v_i^0 = 0, & \tau_i^1 = b_0 \nabla_y v_i^0, \\ v_i^0|_{\partial\Omega_i} = u^0(0, x_2). \end{cases} \quad (26)$$

We used (8a) at the order η^0 and (8b) at the order η^1 , and in both cases, we also used that $\tau_i^0 = \mathbf{0}$, Eq. (18). The boundary condition is given by (14), with (19). This problem is of the Dirichlet type, and it can be solved by noting the linearity of the solution with respect to $u^0(0, x_2)$. As for the Neumann elementary problems, defining

$$v_i^0(\mathbf{y}, x_2) = u^0(0, x_2) V_k(\mathbf{y}), \quad (27)$$

v_i^0 will be solution of (26) as soon as V_k is the solution of the Dirichlet elementary problem

$$\text{in } \Omega_i \quad \begin{cases} \Delta V_k + \kappa^2 V_k = 0, \\ V_k|_{\partial\Omega_i} = 1, \end{cases} \quad (28)$$

with $\kappa^2 \equiv a_i/b_0$. It is worth noting that κ depends implicitly on the frequency or equivalently to the wavenumber k in the matrix, with $\kappa^2 = (\rho_i/\rho_m)(G_m/G_i) (kh)^2$ once coming back to the physical quantities; in other words, κ is the rescaled version of k_i , with

$$\kappa = k_i h. \quad (29)$$

For frequencies κ different of the eigenfrequencies κ_n of (28), the solution is unique and reads

$$V_k(\mathbf{y}) = 1 - \sum_n v_n \frac{\kappa^2}{\kappa^2 - \kappa_n^2} P_n(\mathbf{y}), \quad (30)$$

where the $P_n(\mathbf{y})$ are the eigenfunctions associated to the eigenvalues κ_n^2 and v_n is the projection of P_n on 1 (Appendix A).

We can now determine the jump in σ_1^1 . We start with (8a) at order η^0 in $\Omega \setminus \Omega_i$, integrated on $\Omega \setminus \Omega_i$, namely

$$\int_{\Omega \setminus \Omega_i} d\mathbf{y} \left[\operatorname{div}_{\mathbf{y}} \boldsymbol{\tau}^1 + \frac{\partial \tau_2^0}{\partial x_2} + u^0(0, x_2) \right] = 0, \quad (31)$$

where we used (19). Let us inspect the three integrals in (31); the first integral $\int_{\Omega \setminus \Omega_i} d\mathbf{y} \operatorname{div}_{\mathbf{y}} \boldsymbol{\tau}^1$ can be expressed as follow

$$\int_{\Omega \setminus \Omega_i} d\mathbf{y} \operatorname{div}_{\mathbf{y}} \boldsymbol{\tau}^1 = \int dy_2 \left[\tau_{1|y_1^m}^1 - \tau_{1|-y_1^m}^1 \right] + \int_{\partial \Omega_i} \boldsymbol{\tau}_i^1 \cdot \mathbf{n}, \quad (32)$$

where we used the periodicity of $\boldsymbol{\tau}^1$ with respect to y_2 and the continuity relation $\boldsymbol{\tau}^1 \cdot \mathbf{n}|_{\partial \Omega_i} = \boldsymbol{\tau}_i^1 \cdot \mathbf{n}|_{\partial \Omega_i}$, Eq. (14). The second term in (32) can be expressed as a function of V_k by integrating the relation $\operatorname{div}_{\mathbf{y}} \boldsymbol{\tau}_i^1 + a_i v_i^0 = 0$ (from (26)) over Ω_i . This leads to $\int_{\partial \Omega_i} \boldsymbol{\tau}_i^1 \cdot \mathbf{n} = a_i \int_{\Omega_i} v_i^0$ (with $\mathbf{n}$ being inward), and with v_i^0 in (27), to

$$\int_{\partial \Omega_i} \boldsymbol{\tau}_i^1 \cdot \mathbf{n} = a_i u^0(0, x_2) \int_{\Omega_i} d\mathbf{y} V_k.$$

The second integral in (31) reads

$$\int_{\Omega \setminus \Omega_i} d\mathbf{y} \frac{\partial \tau_2^0}{\partial x_2} = \frac{\partial^2 u^0}{\partial x_1 \partial x_2}(0, x_2) \int_{\Omega \setminus \Omega_i} d\mathbf{y} \frac{\partial V^{(1)}}{\partial y_2} + \frac{\partial^2 u^0}{\partial x_2^2}(0, x_2) \int_{\Omega \setminus \Omega_i} d\mathbf{y} \left[\frac{\partial V^{(2)}}{\partial y_2} + 1 \right], \quad (33)$$

where we used that $\tau_2^0 = [\partial_{y_2} v^1 + \partial_{x_2} u^0(0, x_2)]$, from (21), with v^1 given by (22). Finally, the third integral in (31), with $u^0(0, x_2)$ being independent of $\mathbf{y}$, simply reads

$$\int_{\Omega \setminus \Omega_i} d\mathbf{y} u^0(0, x_2) = u^0(0, x_2) (2y_1^m - \mathcal{S}_i), \quad (34)$$

where $\mathcal{S}_i$ and $(2y_1^m - \mathcal{S}_i)$ are the dimensionless surfaces (in $\mathbf{y}$ coordinates) of Ω_i and $\Omega \setminus \Omega_i$, respectively. Collecting the three integrals (32)-(34), we get

$$\begin{aligned} \int dy_2 \left[\tau_{1|y_1^m}^1 - \tau_{1|-y_1^m}^1 \right] - 2y_1^m \frac{\partial \sigma_1^0}{\partial x_1}(0, x_2) = & -\mathcal{S}_i \frac{\partial^2 u^0}{\partial x_1^2}(0, x_2) - a_i u^0(0, x_2) \int_{\Omega_i} V_k \\ & - \frac{\partial^2 u^0}{\partial x_1 \partial x_2}(0, x_2) \int_{\Omega \setminus \Omega_i} \frac{\partial V^{(1)}}{\partial y_2} - \frac{\partial^2 u^0}{\partial x_2^2}(0, x_2) \int_{\Omega \setminus \Omega_i} \frac{\partial V^{(2)}}{\partial y_2}, \end{aligned} \quad (35)$$

where we have used $\partial_{x_2}^2 u^0 + u^0 = -\partial_{x_1}^2 u^0 = -\partial_{x_1} \sigma_1^0$ from (12). It is now sufficient to take the limit $y_1^m \rightarrow +\infty$ in (36) (integrated over $y_2 \in (0, 1)$), with $\left[\tau_{1|y_1^m}^1 - y_1^m \partial_{x_1} \sigma_1^0(0, x_2) \right] \rightarrow \sigma_1^1(0, x_2)$ and $\left[\tau_{1|-y_1^m}^1 + y_1^m \partial_{x_1} \sigma_1^0(0, x_2) \right] \rightarrow \sigma_1^1(0, x_2)$, to get the jump of $\partial_{x_1} u^1 = \sigma^1$

$$\left[\frac{\partial u^1}{\partial x_1} \right]_0 = -\mathcal{S}_i \frac{\partial^2 u^0}{\partial x_1^2}(0, x_2) + C_1 \frac{\partial^2 u^0}{\partial x_1 \partial x_2}(0, x_2) + C_2 \frac{\partial^2 u^0}{\partial x_2^2}(0, x_2) - \mathcal{D}(k) u^0(0, x_2), \quad (36)$$

where we have defined the dimensionless parameters

$$C_i \equiv - \int_{\Omega \setminus \Omega_i} d\mathbf{y} \frac{\partial V^{(i)}}{\partial y_2}(\mathbf{y}), \quad i = 1, 2, \quad \text{and} \quad \mathcal{D}(k) \equiv \frac{\rho_i}{\rho_m} \int_{\Omega_i} d\mathbf{y} V_k(\mathbf{y}). \quad (37)$$

This provides the second jump condition, and as (25), it is expressed across a zero thickness interface at $x_1 = 0$.

2.5. The homogenized problem and the associated final jump conditions

The final jump conditions will be written, from (25) and (36), in a different and equivalent form up to $O(\eta^2)$. From (9), we have

$$u = u^0 + \eta u^1 + O(\eta^2), \quad (38)$$

and, from (12), (25) and (36), u satisfies

$$\begin{cases} \Delta u + u = 0, \\ \llbracket u \rrbracket_0 = \eta \mathcal{B}_1 \frac{\partial u^0}{\partial x_1}(0, x_2) + \eta \mathcal{B}_2 \frac{\partial u^0}{\partial x_2}(0, x_2) + O(\eta^2), \\ \left\llbracket \frac{\partial u}{\partial x_1} \right\rrbracket_0 = -\eta \mathcal{S}_1 \frac{\partial^2 u^0}{\partial x_1^2}(0, x_2) + \eta \mathcal{C}_1 \frac{\partial^2 u^0}{\partial x_1 \partial x_2}(0, x_2) + \eta \mathcal{C}_2 \frac{\partial^2 u^0}{\partial x_2^2}(0, x_2) - \eta \mathcal{D}(k) u^0(0, x_2) + O(\eta^2). \end{cases} \quad (39)$$

As written in (39), the homogenized problem could be solved using an iterative process: first, compute u^0 and its spatial derivatives along $x_1 = 0$ to get the right hand side terms of the jump conditions (compute also the parameters $\mathcal{B}_i$, $\mathcal{C}_i$, $i = 1, 2$ and $\mathcal{D}$), then compute u up to $O(\eta^2)$. It has been discussed in David et al. (2012) that such resolution is not satisfactory. Firstly because it requires the numerical computation of spatial derivatives of the fields at $x_1 = 0$ which is demanding for continuous fields, as u^0 , and may become technically involved for discontinuous fields, as u^1 which will be required for the jump condition on u^2 (and this remark is not incidental in the present case, see Section 4). Instead, David et al. (2012) propose the construction of a unique problem for a field u^h admitting the same expansion as $u^0 + \eta u^1$ up to $O(\eta^2)$ (and thus, the same expansion as the real field u). Besides, it is stressed that this problem admits a variational formulation, which allows to define an energy being the sum of the usual elastic energy and a surface energy supported by the equivalent interface. Also, it has been shown that it is preferable to express the jump conditions across an enlarged version of the interface (Fig. 4). In Delourme et al. (2012), this is done to ensure stability properties of the obtained conditions with respect to η and with respect to the frequency; in Marigo and Maurel (2016a), this is done in order to ensure a positive energy supported by the interface, see also Marigo et al. (2016). In both cases, an important consequence is to get a formulation suitable for numerical implementations (Lombard et al., 2016). The two above mentioned aspects will be addressed. First, we define an enlarged version of the jumps and associated average value for any field $f(x_1, x_2)$

$$\llbracket f \rrbracket \equiv f^+ - f^-, \quad \bar{f} \equiv \frac{1}{2} [f^- + f^+], \quad \text{with} \quad f^\pm = f\left(\pm \frac{ke}{2}, x_2\right). \quad (40)$$

Now, we use the Taylor expansion

$$u^0\left(\pm \frac{ke}{2}, x_2\right) = u^0(0^\pm, x_2) \pm \eta \frac{e}{2h} \frac{\partial u^0}{\partial x_1}\left(\pm \frac{ke}{2}, x_2\right) + O(\eta^2), \quad (41)$$

where we used $e/h = O(1)$, and from (39), we get the jump condition

$$\llbracket u \rrbracket = \eta \left(\mathcal{B}_1 + \frac{e}{h} \right) \overline{\frac{\partial u}{\partial x_1}} + \eta \mathcal{B}_2 \overline{\frac{\partial u}{\partial x_2}} + O(\eta^2), \quad (42)$$

(and the same is done to get the jump of $\llbracket \partial u / \partial x_1 \rrbracket$).

Figure 4: (a) Initial jump conditions (39) across a zero thickness interface at $x_1 = 0$, (b) Final jump conditions (3) across the enlarged interface.

Now, we define the new homogenized problem

$$\begin{cases} \Delta u^h + u^h = 0, \\ \llbracket u^h \rrbracket = \eta \left(\mathcal{B}_1 + \frac{e}{h} \right) \overline{\frac{\partial u^h}{\partial x_1}} + \eta \mathcal{B}_2 \overline{\frac{\partial u^h}{\partial x_2}}, \\ \left[\left[\frac{\partial u^h}{\partial x_1} \right] \right] = \eta \left(\frac{e}{h} - \mathcal{S}_i \right) \overline{\frac{\partial^2 u^h}{\partial x_1^2}} + \eta \mathcal{C}_1 \overline{\frac{\partial^2 u^h}{\partial x_1 \partial x_2}} + \eta \mathcal{C}_2 \overline{\frac{\partial^2 u^h}{\partial x_2^2}} - \eta \mathcal{D}(k) \overline{u^h}. \end{cases} \quad (43)$$

It is easy to see that u^h admits the same expansion as u up to $O(\eta^2)$ and (43) is our homogenized problem in rescaled coordinate. It is now sufficient to come back to the real space to get the final homogenized problem consists in solving, outside the interface occupying $\mathbf{X} \in (-e/2, e/2) \times (-\infty, +\infty)$

$$\begin{cases} \Delta U^h + k^2 U^h = 0, & \frac{e}{2} < |X_1|, \\ \llbracket U^h \rrbracket_e = h \mathcal{B}'_1 \overline{\frac{\partial U^h}{\partial X_1}} + h \mathcal{B}_2 \overline{\frac{\partial U^h}{\partial X_2}}, \\ \left[\left[\frac{\partial U^h}{\partial X_1} \right] \right]_e = h \mathcal{S} \overline{\frac{\partial^2 U^h}{\partial X_1^2}} + h \mathcal{C}_1 \overline{\frac{\partial^2 U^h}{\partial X_1 \partial X_2}} + h \mathcal{C}_2 \overline{\frac{\partial^2 U^h}{\partial X_2^2}} - h \mathcal{D}(k) k^2 \overline{U^h}, \end{cases} \quad (44)$$

with $\mathcal{B}'_1 \equiv e/h + \mathcal{B}_1$, $\mathcal{S} = e/h - \mathcal{S}_i$ ($\mathcal{B}_i$, $\mathcal{C}_i$, $i = 1, 2$ and $\mathcal{D}$ have been defined in (24) and (37)), and where $\llbracket F \rrbracket \equiv F(e/2, X_2) - F(-e/2, X_2)$ and $\overline{F} \equiv 1/2 [F(e/2, X_2) + F(-e/2, X_2)]$.

2.6. The case of symmetrical inclusions

In the case of inclusions being symmetric with respect to y_2 , the effective parameters $\mathcal{C}_1$ and $\mathcal{B}_2$ vanish, leading to the form in (3), with $\mathcal{B} = \mathcal{B}'_1$ and $\mathcal{C} = \mathcal{C}_2$. This is because the elementary solutions $V^{(1)}$ and $V^{(2)}$ in (23) are respectively symmetric and antisymmetric with respect to y_2 .

This implies that $\mathcal{B}_2 = 0$ in (24) because $V^{(2)}(y_1, 0) = 0$, and $C_1 = 0$ in (37) since $\partial_{y_2} V^{(1)}$ is odd in y_2 (thus its integral vanishes). Besides, the expressions of these parameters for rectangular inclusions, as we shall consider in the following section, are known (Marigo and Maurel, 2016a) and they have been given in Eqs. (4); note that better estimates of $(\mathcal{B}, \mathcal{C})$ can be obtained by solving numerically the elementary problems (24) while $\mathcal{D}$ is obtained explicitly, see Appendix A.

3. Validation of the homogenized interface problem

In this section, we address the validity of our homogenized problem (3) with respect to the real one. This is done considering two classical problems for wave propagating in such an array of locally resonant inclusions: (i) the scattering of incident plane waves and (ii) the propagation of guided waves supported by the array. In both cases, the effect of losses in the inclusions is regarded and this is relevant in view of practical applications. In the former case, the absorption resulting from the losses is known to be significant near the resonance, resulting in an efficient thin "metamaterial absorber" able to block the wave propagation over a short distance, and short is meant when compared to the wavelength. In the latter case, the losses are unwanted since they produce energy leakage from the array along which the guided wave propagates; this may produce the suppression of the guiding effect. In both cases, a theoretical prediction on the effects of resonances of lossy inclusions is proposed, owing to the explicit solutions available in the homogenized problem.

Figure 5: The array composed of a single row of rectangular locally resonant inclusions.

We shall consider an array of square, or rectangular, inclusions (Fig. 5). A contrast in the shear modulus $G_m/G_i = 100$ with $\rho_m/\rho_i = 1$ is considered; it is a rather modest contrast which could be obtained with soft silicon rubber inclusions in a hard silicon matrix (Lai et al., 2011). In electromagnetism, this contrast is obtained with non magnetic inclusions of TiO_2 in the air (Lannebère et al., 2014). When the effect of losses is regarded, only the losses in the inclusions are considered, being encapsulated in a complex value of $1/G_i = (1 + i\xi)/G_0$, resulting in a complex wavenumber k_i in the inclusions. The actual problem of the array of locally resonant inclusions is solved numerically using full wave calculations (Maurel et al., 2014), and we denote U^{num} the wavefield of the numerical solution. The solution of the homogenized problem satisfies (3), with the interface parameters in (4)-(5).

3.1. Reflection, transmission and absorption of an incident plane wave

In our homogenized problem, the region $|X_1| < e/2$ is disregarded and the wavefield satisfies (3) for $|X_1| > e/2$; a solution of this problem for an incident plane wave at oblique incidence θ

reads

$$U^h(\mathbf{X}) = \begin{cases} \left[e^{ik(X_1+e/2)\cos\theta} + R^h e^{-ik(X_1+e/2)\cos\theta} \right] e^{ikX_2\sin\theta}, & X_1 < -\frac{e}{2} \\ T^h e^{ik(X_1-e/2)\cos\theta} e^{ikX_2\sin\theta}, & \frac{e}{2} < X_1, \end{cases} \quad (45)$$

and this solution is thought to (i) satisfy the condition of pseudo periodicity $U^h(X_1, X_2 + h) = U^h(X_1, X_2)e^{ik\sin\theta h}$ imposed by the form of the incident wave $U^{\text{inc}} = e^{ik\cos\theta(X_1+e/2)+ik\sin\theta X_2}$, and (ii) to satisfy the radiation condition for $|X_1| \rightarrow +\infty$ of outgoing scattered waves ($U^h - U^{\text{inc}}$).

Next, applying the jump conditions (3) yields the scattering coefficient

$$\begin{cases} R^h = -\frac{1}{2} \left[\frac{z_1}{z_1^*} - \frac{z_2 - z_2'}{z_2^* + z_2'} \right], & T^h = \frac{1}{2} \left[\frac{z_1}{z_1^*} + \frac{z_2 - z_2'}{z_2^* + z_2'} \right], \\ z_1 \equiv 1 + i\frac{kh}{2} \mathcal{B} \cos\theta, \\ z_2 \equiv \cos\theta + i\frac{kh}{2} [\mathcal{S} \cos^2\theta + C \sin^2\theta + \mathcal{D}_r(k)], & z_2' = \frac{kh}{2} \mathcal{D}_i, \end{cases} \quad (46)$$

where z^* denotes the complex conjugate of z . We used that the presence of losses in the inclusions affects only the parameter $\mathcal{D} = \mathcal{D}_r + i\mathcal{D}_i$ according to (5), since $k_i^2 = k_{i0}^2(1 + i\xi)$ is complex. Note that, near the first Mie resonance, $\mathcal{D}_r$ and $\mathcal{D}_i$ can be approximated by

$$\mathcal{D}_r(k) \simeq A \left[1 - \alpha_1^2 \frac{(k^2/k_m^2 - 1)}{(k^2/k_m^2 - 1)^2 + \xi^2} \right], \quad \text{and} \quad \mathcal{D}_i(k) \simeq A\alpha_1^2 \frac{\xi}{(k^2/k_m^2 - 1)^2 + \xi^2}, \quad (47)$$

with $A \equiv e\varphi/h$ and where $k_m^2 \equiv (\rho_i/G_0)k_{i,1}^2$ is the wavenumber (being real) in the elastic matrix producing the first, monopolar resonance in the inclusions. It is worth noting that in absence of attenuation, $z_2' = 0$ and we recover $|R^h|^2 + |T^h|^2 = 1$ as expected.

To begin with, we report in Fig. 6 the variations of the reflection coefficients in the absence of losses as a function of the dimensionless frequency kh , R^{num} being computed numerically and R^h from (46). In the range $kh \in [0, 1.2]$, the first monopolar resonance for $n = (1, 1)$ in (5) is visible (it occurs for $k_i h = 8.9$ whence $kh \simeq 0.9$, resulting in a wavelength within the inclusions being about half the inclusion length). The agreement between R^{num} and its homogenized counterpart R^h is good, about 2% for $kh < 1$ for the two reported incidences $\theta = 0$ and 40° (the visible higher discrepancy observed for $kh > 1$ will be commented in Section 4). Next, the homogenized result is valid for any incidence θ , as illustrated in Fig. 6(c) with no loss of accuracy near the grazing incidence.

The resonance, of the Mie type, has the typical asymmetric shape of a Fano resonance and produces within a small frequency band a perfect transmission followed by a complete extinction. The corresponding wavefields are shown in Fig. 7; expectedly, the wavefields U^{num} calculated numerically (left panels in Figs. 7) are accurately reproduced by their homogenized counterparts U^h from (45)-(46) (right panels in Figs. 7), since we have already seen that they have the same scattering coefficients. The error $|U^{\text{num}} - U^h|$ (with L^2 norm) calculated for $|X_1| > e/2$ is about 5%; The error is slightly higher than the error in the scattering coefficients, because it accounts for the evanescent fields near the inclusions.

To go further, it is of interest to inspect whether or not our homogenized solution is able to encapsulate the effect of losses, usually measured by the absorption $\mathcal{A} = 1 - |R|^2 - |T|^2$; in our

Figure 6: Reflection coefficient as a function of the dimensionless frequency kh . $|R^{\text{num}}|$ being computed numerically (symbols) and $|R^h|$ in the homogenized problem, Eq. (46) (black line); the incident angle is (a) $\theta = 0$ and (b) $\theta = 40^\circ$. (c) shows the reflection coefficients as a function of θ for $kh = 0.7$. The inclusions are square, with $e/h = \varphi = 0.5$, and no loss $\xi = 0$.

Figure 7: Wavefields U^{num} computed numerically in the real problem (left panels in (a-b), $X_2 < 0$), and U^h solution of the homogenized problem, Eqs. (45) -(46) (right panels in (a-b), $X_2 > 0$). The incident wave hits the array at oblique incidence $\theta = 40^\circ$, (a) for $kh = 0.7$ realizing perfect transmission and (b) for $kh = 0.9$ realizing perfect reflection (the color scales are $M=1$ and 2 respectively).

homogenized problem, with (46), it is

$$\mathcal{A} \equiv 1 - |R^h|^2 - |T^h|^2 = -\frac{2 \cos \theta z'_2}{|z_2|^2 + z_2'^2 + 2 \cos \theta z'_2}. \quad (48)$$

Fig. 8(a) exemplifies the accuracy of the above expression (48) at normal incidence and near the grazing incidence. As expected, the maximum of absorption occurs in the vicinity of $k = k_m$ with a slight dependence on the incident angle. Beyond its dependence on the wavenumber, the maximum of absorption depends on the attenuation ξ in a non-trivial way. A counter-intuitive effect of absorption has already been observed before by Christensen et al. (2014) who reported an increase in the absorption when less lossy material was used. The explicit form of the attenuation (48) in the homogenized problem allows us to anticipate that increasing the losses ξ in the inclusions does not produce a systematic increase in the attenuation ($\mathcal{A} \rightarrow 0$ for both $\xi \rightarrow 0$ and $\xi \rightarrow +\infty$, since $z'_2 \propto \mathcal{D}_i$ vanishes in both cases, according to (47)). In Fig. 8(b), the maximum of absorption with respect to ξ is shown to depends in addition on θ , and we observe again a good agreement between the real and homogenized solutions.

Figure 8: (a) Absorption $\mathcal{A}$ as a function of kh for $\theta = 0$ and 80° , computed from U^{num} (symbols) and given by the homogenized solution Eq. (48) (black lines), (b) Maximum absorption as a function of the attenuation ξ (same representation).

3.2. Guided waves and energy leakage for lossy inclusions

Let us start with the solution of the homogenized problem. If they exist, guided waves are solutions of the homogeneous problem (3), that is the problem in the absence of a wave source. Specifically, they read

$$U^h(\mathbf{X}) = \begin{cases} e^{\gamma(X_1 + e/2) + i\beta X_2} & X_1 < -\frac{e}{2}, \\ Ae^{-\gamma(X_1 - e/2) + i\beta X_2} & X_1 > \frac{e}{2}, \end{cases} \quad (49)$$

with β the wavenumber of the guided wave. The above form of the solution imposes $\gamma_r \equiv \text{real}(\gamma) > 0$ that is waves vanishing at $|X_1| \rightarrow +\infty$. Next, U^h satisfies (3) with $A = 1$ and the dispersion relation $\beta = \beta(k)$ with

$$\beta = \sqrt{\gamma^2 + k^2}, \quad \text{with } \gamma = \frac{\sqrt{\delta} - 1}{h(S - C)}, \quad \delta \equiv 1 + (S - C)(C + \mathcal{D})(kh)^2. \quad (50)$$

With $S - C \simeq \frac{\pi}{8}(1 - \varphi)^2 > 0$ (this property is general for any inclusion shape, see Marigo et al. (2016)), we have γ_r positive if $C + \mathcal{D}_r > 0$.

A typical field of a wave guided along the resonant inclusions is reported in Fig. 9 in the lossless case. The solution U^{num} has been calculated numerically by considering the scattering problem, Eq. (45), and replacing $k \sin \theta$ by β (and $\beta > k$) whence $k \cos \theta$ is replaced by $i\sqrt{k^2 - \beta^2} = -\gamma$; while the incident wave is unphysical (because of the form $e^{-\gamma X_1}$ thus diverging for $X_1 \rightarrow -\infty$), it produces diverging values of (R^h, T^h) which are the witnesses of the guided wave (Mercier et al., 2015). We also reported the solution U^h in the homogenized problem, being simply given by (49) with (50). A good agreement between both wavefields is obtained, and we shall see below that the dispersion relation (50) is indeed accurate.

We now inspect the validity of the dispersion relation (50). In the lossless case, $\mathcal{D} = \mathcal{D}_r$ is approximated by (47) with $\xi = 0$. Far from the resonance, $\mathcal{D}$ is positive but of order unity, from which $\epsilon \equiv (S - C)\mathcal{D}(kh)^2 \ll 1$ producing $\gamma \simeq 0$ in (50). Thus, $\beta \simeq k$ remains close to the so-called sound line (the line $\beta = k$ which defines the frontier between propagating waves

Figure 9: Wavefields of the wave guided within the array; U^{num} computed numerically in the real problem (left panel, $X_2 < 0$), and U^h solution of the homogenized problem, Eqs. (49) -(50) (right panels, $X_2 > 0$). The inclusions are rectangular with $e/h = 0.5$ and $\varphi = 0.9$; with $kh = 0.7$, the wavenumber of the guided wave is $\beta h = 1.43$.

$\beta < k$ and evanescent waves $\beta > k$). When k approaches k_m , $\mathcal{D}$ increases with positive value (see Eq. (47)), and β/k does the same. This β/k value measures the efficiency of the guiding effect: high β value corresponds to surface waves highly confined in the vicinity of the array. Finally, just above $k = k_m$, $\mathcal{D}$ becomes infinite and negative, which defines the asymptote above which a band gap is created (until $(C + \mathcal{D})$ becomes positive again at higher frequency). We now inspect the lossy case. Guided waves being based on a resonant behavior are sensitive to losses. This is because γ acquires an imaginary part which produces the leakage of the energy toward $|X_1| \rightarrow +\infty$. As a rule of thumb, we can estimate that the guiding effect becomes inefficient when $\gamma_i > \gamma_r$ (with $\gamma = \gamma_r + i\gamma_i$). In (47), it is sufficient to remark that in presence of losses, $\mathcal{D}$ remains finite, and ϵ defined above satisfies $|\epsilon| \ll 1$ for ξ large enough; in (50), we get $\delta = 1 + \epsilon$ and $\gamma \simeq \epsilon/(2h(S - C))$ whence

$$\gamma \simeq \frac{1}{2} \mathcal{D} k^2 h. \quad (51)$$

It follows that $\gamma_r < \gamma_i$ when $\mathcal{D}_r < \mathcal{D}_i$ which may occur near the resonance only, from (47), when $k > k_m \sqrt{1 - \xi}$.

Results are reported in Fig. 10. The dispersion relation in the real problem is visible by means of diverging (in the lossless case) or large (in the lossy case) values of the scattering coefficients when an incident evanescent wave is considered (as in Fig. 9); in Fig. 10, $\log |R^{\text{num}}|$ is reported in colorscale in the $(kh, \beta h)$ plane, and the red regions reveal the shape of the dispersion relation. The dispersion relation in the homogenized problem, Eq. (50), is also reported (black lines) applying the criterion $k < k_m \sqrt{1 - \xi^2}$ for an efficient guiding effect. The agreement is good but remains qualitative since the criterion for the disappearance of guided waves is obviously quite subjective.

To end the comparison, it is worth noting that (R^h, T^h) can be calculated from (46) using the same trick as used to compute $(R^{\text{num}}, T^{\text{num}})$ in the real problem (namely using $k \cos \theta \rightarrow i\gamma$, $k \sin \theta \rightarrow \beta$ in (46)). We get in the plane $(kh, \beta h)$ the wave properties for propagating waves when $\beta < k$ and guided wave when $\beta > k$. The results are not reported since they are indiscernible at naked eyes to the result reported in Fig. 10. We get $|R^h - R^{\text{num}}|/|R^{\text{num}}|$ averaged in the whole plane of 20% for $\xi = 0.025$, 6% for $\xi = 0.1$, and 3% for $\xi = 0.75$ (the comparison is not possible for $\xi = 0$). The increase in the error for small ξ is mainly attributable to numerical errors for $\beta > k$.

4. Concluding remarks and perspectives

We have proposed a homogenization of an array of locally resonant inclusions with high contrast in its shear modulus compared to the matrix; this produces wavelengths inside the soft inclusions of the same order of magnitude as their typical size. Such homogenization leads to

Figure 10: For (a-d), the left panel reports the reflection coefficient $\log |R^{\text{num}}|$ (colorscale) in the plane (k, β) ; the dispersion relation of the guided wave is visible by means of high values of $|R^{\text{num}}|$. The dispersion relation of the guided wave in the homogenized problem, Eq. (50) are reported in black lines, together with the condition $k < k_m \sqrt{1 - \xi}$ (see the main text). For (a-d) the right panel shows the real part (solid line) and the imaginary part (dotted line) of γ as a function of kh ; the guiding effect becomes inefficient for $\gamma_i > \gamma_r$.

an equivalent problem in which jump conditions apply across the region originally occupied by the array. The homogenized problem has been validated by comparison with direct numerical calculations, and we addressed the case of lossy inclusions.

There are at least three natural extensions of the present study, being of different nature. One of them is technically rather incremental. We considered shear waves in a binary structures but the present work can be extended without technical difficulties to three dimensional case and to ternary structure, as proposed in Liu et al. (2000). This extension may be of particular interest when locally resonant materials are considered in the acoustic case; as previously said, this is obtained in practice considering binary or ternary structures mixing fluids and elastic materials, thus for which the conversions between shear and longitudinal waves have to be accounted for. We believe that this is the key point to properly describe the negative index material reported in this context (Ding et al., 2007).

The second extension is not demanding at all theoretically but it deserves interest. As previously said, effective medium theories have been applied to locally resonant materials to get effective mass densities ρ_{eff} and effective shear moduli G_{eff} . Although these results hold when the resonant material occupies a thick slab, it is tempting to see if (i) it is possible to replace

our effective jump conditions by the usual continuity relations (of the displacement and of the normal stress) at the boundary of a slab filled with some homogeneous effective medium and (ii) if/when the case, how the resulting effective mass density and shear modulus compare with the values $(\rho_{\text{eff}}, G_{\text{eff}})$ previously derived in Auriault and Boutin (2012) and in Felbacq and Bouchitté (2005).

The third extension is technically much demanding. Our result has a serious limitation, in fact the same as in Auriault and Boutin (2012) and Felbacq and Bouchitté (2005) (and this was already pointed out in this latter reference). The analysis holds for resonances with non null mean value (namely, n_1 and n_2 odd in (5)); this is illustrated in Fig. 11, where the resonances with null mean value are clearly not described by the homogenized solution. Although these resonances have a higher quality factor and thus are much more sensitive to losses (see Fig. 11(b)), the accuracy of the homogenized solution would be greatly enhanced if one is able to account for them. This requires to develop the homogenization model up to the second order in η and this is not incremental. For the time being, the model is limited to the first monopolar resonance, and this holds for the homogenization of thick structures.

Figure 11: Reflection coefficient $|R^{\text{num}}|$ (symbols) and $|R^h|$ (black lines) as a function of the dimensionless frequency kh (same representation as in Fig. 6 extended to the first 4 resonances). (a) without attenuation, the four resonances are visible, parametrized by (n_1, n_2) (the inset shows the corresponding patterns for $|X_1| < e/2$ and $X_2 \in [0, 1]$), among which two are of null spatial means: (2,1) and (2,3). (b) same representation for $\xi = 0.05$.

Appendix A. Solution of the Dirichlet problem for rectangular inclusions

The solution of (28) is easy to find; introducing $U \equiv V_k - 1$, U is solution of

$$\text{in } \Omega_i \quad \begin{cases} \Delta U + \kappa^2 U = -\kappa^2, \\ U|_{\partial\Omega_i} = 0, \end{cases} \quad (\text{A.1})$$

and U can be expanded onto a basis of eigenfunctions $P_n(\mathbf{y})$ being solutions of the eigenvalue problem $\Delta P + \kappa^2 P = 0$ in Ω_i , with $P|_{\partial\Omega_i} = 0$ (we denote κ_n the eigenvalues). The decomposition reads

$$U(\mathbf{y}) = U_n P_n(\mathbf{y}). \quad (\text{A.2})$$

Projecting (A.1) onto the P_n gives the coefficients U_n

$$U_n = -\frac{\kappa^2}{\kappa^2 - \kappa_n^2} (1, P_n), \quad (\text{A.3})$$

with $(.,.)$ the scalar product. In $\mathbf{y}$ coordinates, our rectangular inclusions have dimensions e/h along y_1 and φ along y_2 , and the eigenfunctions are

$$P_n(y_1, y_2) = \frac{2h}{\sqrt{e\varphi}} \sin\left(\frac{n_1\pi h}{e} y_1\right) \sin\left(\frac{n_2\pi}{\varphi} y_2\right),$$

with (n_1, n_2) ordered by n ; for instance $n = 1$ corresponds to $n_1 = n_2 = 1$. We get

$$\begin{cases} \kappa_n^2 = \left(\frac{n_1\pi h}{e}\right)^2 + \left(\frac{n_2\pi}{\varphi}\right)^2, \\ (1, P_n) = \frac{8}{\pi^2} \sqrt{\frac{e\varphi}{h}} \frac{1}{n_1 n_2}, \end{cases} \quad (\text{A.4})$$

for (n_1, n_2) odd. The interface parameter $\mathcal{D}$ in (37) can be calculated

$$\mathcal{D} = \frac{\rho_i}{\rho_m} \int_{\Omega_i} d\mathbf{y} [1 + U_n P_n(\mathbf{y})] = \frac{\rho_i}{\rho_m} \left[S_i - \frac{\kappa^2}{\kappa^2 - \kappa_n^2} (1, P_n)^2 \right], \quad (\text{A.5})$$

with $S_i = e\varphi/h$ and using (A.4), we get

$$\begin{cases} \mathcal{D} = \frac{\rho_i}{\rho_m} \frac{e\varphi}{h} \left[1 - \alpha_n^2 \frac{k_i^2}{k_i^2 - k_{i,n}^2} \right], \\ \text{with } k_{i,n}^2 \equiv \left(\frac{n_1\pi}{e}\right)^2 + \left(\frac{n_2\pi}{h\varphi}\right)^2, \quad \text{and } \alpha_n \equiv \frac{8}{\pi^2 n_1 n_2}, \end{cases} \quad (\text{A.6})$$

with the $k_{i,n}$ being the resonance frequencies in the inclusions, and $n = (n_1, n_2)$ with n_1 and n_2 odd integer.
